State-of-the-art of spread moored systems for deepwater floating production platforms. All floating production platforms (semisubmersible, Spar, FPSO, and TLP) are positioned by a station-keeping system. The primary function of this system is to constrain horizontal platform offsets to a "watch circle" that enables production and export risers to remain connected for the life of the field.

Deepwater Mooring. Deepwater moorings are different from other offshore rope applications. They are long term applications, typically 30 years, and under constant load. Unlike wire and chain mooring systems at shallower depths that rely on the weight of the mooring lines to hold the surface production unit on station, polyester rope taut leg mooring systems use the elasticity of the rope to provide the restoring force needed.

In relation to deepwater moorings, the design practice becomes more important as systems are likely to be taut with highly pretensioned lines. The high pretension level reduces, or in the case of fiber ropes, eliminates compliance due to the weight and geometry driven catenary deformation.

Buzios field is one of the world ’ s biggest deepwater offshore oil fields. Its development has the potential to implement several production systems due to large reservoir volumes. Many offshore platforms close to each other, together with geological hazards in the area, lead to a potentially congested seabed scenario. Hence, Platforms positioning has been challenging and demanding innovative engineering solutions to optimize Platforms mooring as to overcome these challenges and enable ...

Integrated design of mooring and risers is illustrated with an example: an FPSO moored in deep water offshore W. Africa with 16 mooring lines and 20 steel catenary risers (SCRs) installed in stages. An important aspect of the example is that it includes consideration of riser fatigue life in the integrated mooring and riser design.

There are several different anchoring systems that have been developed for deep water applications, where seabeds mostly comprise relatively low strength sediments. The optimum system will depend on the nature of the required mooring, whether temporary or permanent, the form of mooring system, whether catenary or semi-taut, and the magnitude of the operational loading.

Design of Anchoring Systems for Deep Water Soft Sediments ...

In a good design the stiffness contribution from the riser system should be relatively small. An unwanted side effect of the mooring system is the coupling between horizontal displacement and rotation, e.g. between surge and pitch. The vertical components of the mooring line forces introduce heeling and pitching moments.

Since the Engineer ’ s Design Guide (EDG) (Ref 2) has been published back in 1998, a decade ago, a lot has happened with the installation and operation of deepwater mooring systems — now polyester fiber rope mooring systems (as opposed to steel wire rope and chain) have become the technology of choice for deepwater mooring systems.
